ABSTRACT

Quantum theory of the optical stochastic cooling is presented. Results include full quantum analysis of the interaction of the beam with radiation in the undulators and quantum amplifier. The density matrix of the whole system is constructed. Evolution of the density matrix in the quantum amplifier includes non-diagonal components. The description of a bunch in the undulators follows Bambini-Renieri-Dattoli approach (1D regime) and reproduces Becker-McIver results but formalism is different from the later authors. Result shows that quantum fluctuations change classical results of stochastic cooling at low bunch population and sets the limit on the achievable cooling rate.

I. INTRODUCTION

Optical stochastic cooling was proposed recently [1], [2]. In the method, radiation is generated by a particle in a (pickup) undulator and, after amplification in the optical amplifier, is send to another undulator (kicker). In the kicker, amplified wave of radiation interacts with the same particle providing desirable cooling. The phase shift of the off-momentum particle in respect with the wave is controlled in a dispersion section between two undulators.

Effect of radiation of a particle on the other particles in the bunch leads to diffusion and limits the damping rate. In this respect, optical stochastic cooling is not different from the rf stochastic cooling. The number of interacting particles (the number of “particles per slice”) in the bunch with rms length $\sigma_b = c\tau_b$ and bunch population $N_B$ is

$$N_s = \frac{\pi N_b}{\Delta\omega \sqrt{2\pi \tau_b}},$$

and is defined by the bandwidth of the amplifier $\Delta\omega$. The interaction of particles changes momentum of the $j$-th particle [3]

$$\bar{p}_j = p_j - \Lambda p_j - \Lambda \sum_{i \neq j} p_i,$$

where $\Lambda$ is parameter of interaction between particles proportional to the electronic gain of the amplifier. The rms energy spread $\sigma_p^2 = (1/N_b) \sum_j [<(p_j)^2> - <p_j>^2]$ for initially uncorrelated particles is changed by
\[ \Delta[\sigma_p^2] = -2\Lambda\sigma_p^2 + \Lambda^2 N_s\sigma_p^2. \] (3)

The cooling rate is
\[
\frac{1}{N_{\text{turn}}} = \frac{\Delta\sigma_p^2}{\sigma_p^2} = -2\Lambda + \Lambda^2 N_s. \quad (4)
\]

The maximum cooling rate \(1/N_{\text{turn}} = 1/N_s\) is determined by the number of particles per slice, and is achieved at \(\Lambda = 1/N_s\).

Cooling of a short bunch requires large bandwidth of the amplifier. For example, the bunches in the PEP-II B-factory have \(\tau_b = 33\) ps. To affect different slices in the bunch, \(N_s\) has to be small, \(N_s < N_b\), what requires \(\Delta\omega/2\pi > 10\) GHz. The actual PEP-II bandwidth is only 250 MHz.

In the case of the optical stochastic cooling, the bandwidth \(\Delta f \simeq \gamma_0^2(c/L_u)\) where \(L_u = N_u\lambda_u\) is the undulator length and \(\gamma_0\) is relativistic factor of the beam in the laboratory frame. The advantage of the optical stochastic cooling is large \(\Delta f\) allowing fast cooling. Parameters of the undulator has to be chosen to match the undulator mode to the central frequency and bandwidth \(\Delta f\) of the amplifier. For the typical solid state Ti:Sapphire amplifier \((\lambda = 0.8\mu, \Delta f/f \simeq 1/5)\).

Given bandwidth, the fast cooling (for example, for the muon collider) can be achieved reducing \(N_s\). However, with small number of particles per slice, classical and quantum fluctuations could become dangerous. For example, in the limit of one particle per slice, the cooling would be achieved just in one turn. However, the average number of photons radiated in the main undulator mode is \(\alpha_0 = 1/137\). Therefore, one can expect that a photon is radiated once per 137 turns, and fluctuations may be large.

Concern with the quantum fluctuations is the primary motivation of the study we present here. Related problem might be the amplification of the noise induced by interaction of particles in the undulator and by the noise of the amplifier.

In our consideration we follow the evolution of the quantum-mechanical density matrix of the system (bunch plus radiated mode) through the undulators and quantum amplifier. The paper starts with the definition of the initial density matrix of the beam, and then by description of the beam/radiation interaction in undulator. Dynamics in the undulators is described as 1D dynamics in the rest frame of a bunch as it is outlined by Dattoli-Renieri [4], [5] where other references can be found. The formalism [7] we use to describe radiation of the beam in the undulators reproduces results but is different from Becker and McIver [6] formalism. In our formalism as well as in the Becker-McIver’s formalism, the number of particles per bunch \(N_s\) can be arbitrary, but effect of bunching is neglected. In this sense the interaction of particles with radiation is weak. This assumption substantially simplifies consideration being quite adequate for describing optical stochastic cooling. After that, we describe the evolution of the density matrix in the quantum amplifier taking into account non-diagonal components of the density matrix. Interaction of the amplified radiation with the bunch in the kicker is considered in the following section in the same way as it was done for the pickup undulator. At the end, the full density matrix is constructed and is used to obtain the optimum cooling rate of the system. All phase relations are retained through the whole system. In conclusion, we compare the final result for the rms energy spread with the classical theory and discuss effect of quantum fluctuations.

**II. INITIAL DENSITY MATRIX OF A BUNCH**

We consider only longitudinal motion in a bunch assuming that the bunch of \(N_b\) particles is described by the Gaussian normalized distribution function (d.f.) \(f(p, z)\),
\[
\int f(p, z)dpdz = 1. \quad (5)
\]

The classical d.f. \(f\) is related to Wigner’s density matrix \(\hat{\rho}\). In the momentum representation, the relation is
\[
f(p, z) = \int \frac{Ldq}{(2\pi)^2}\rho(p + q/2, p - q/2)e^{iqz/h}. \quad (6)
\]
where the density matrix is normalized,
\[
\hat{\rho} = |p' > \rho(p', p) < p|, \quad \int \frac{Ldp}{2\pi}\rho(p, p) = 1. \quad (7)
\]
For a Gaussian d.f. localized around the point \(z_0, p_0\) in the phase space,
\[ f(p, z) = \frac{1}{2\pi\sigma\Delta} e^{-\frac{(p-p_0)^2 + (z-z_0)^2}{2\sigma^2 \Delta^2}}. \]  

The corresponding density matrix \( \rho_0 \) is the wave packet

\[ \rho_0(p', p) = \frac{\hbar \sqrt{2\pi}}{L\Delta} e^{-\frac{1}{2}[(p'-p)\sigma_0 - \frac{1}{2}(p')^2 + \frac{1}{2}(p_0' - p_0)^2].} \]

III. PICKUP

We assume that, at the entrance to the pickup, there are \( N_B \) relativistic particles, there is no initial \( z, p \) correlation, and correlations generated in one pass are wiped out in one turn. The pickup (and the kicker) undulators are helical with the undulator parameter \( K_0 \) and period \( \lambda_u = 2\pi/k_u \). The bunch dynamics is considered in the moving [5] frame with the relativistic factor \( \gamma = \gamma_0/\sqrt{1 + K_0^2} \), where the bunch centroid initially has zero velocity, and the resonance frequency of the mode is \( k = \kappa k_u \). The energy spread \( \Delta p \),

\[ \Delta p = \frac{1}{\sqrt{1 + K_0^2}} \left( \frac{\Delta p_{lab}}{\gamma} \right), \]

corresponds to the energy spread \( \Delta p_{lab} \) in the laboratory frame.

At the entrance to the pickup, each particle is described by the density matrix Eq. (9), \( \hat{\rho}'(p'_i, p_i) = \rho(0, p'_i, p_i) < p \).

In the moving frame, interaction of particles with the mode \( k = \omega/c \) is described by the Hamiltonian

\[ H = \sum_{i=1}^{N_B} \frac{\hat{p}_i^2}{2m} + \hbar \omega (a^+ a + 1/2) - i\hbar g[ae^{ik_0z} + icc], \]

where \( m = m_e \sqrt{1 + K_0^2} \).

If the vector-potential of the radiation is normalized to one photon per volume \( V \) [6], [7]

\[ \hat{A} = \sqrt{\frac{2\pi\hbar c^2}{V\omega}} \hat{g} a e^{ik_0z} + cc, \quad |\hat{g}| = 1, \]

then parameter of interaction

\[ g_k = \frac{\gamma k_0}{\sqrt{1 + K_0^2}} \sqrt{\frac{e^2 2\pi}{\hbar c k V}}. \]

We are going to consider 1D model where beam interacts with a single radiated mode. In this case, operator \( a, a^+ \) are operators changing number of coherent photons in the mode, and the vector potential has to be normalized to the phase volume \( \Omega \) of the mode.

In the laboratory frame [11], \( \Omega = \frac{V}{(2\pi)^3}(\pi k^3/N_B^2) \). The later follows in the laboratory frame from the constrain \( |2\pi N_a - \psi| = \pi \) on the phase slippage \( \psi = |\omega t - k_0 z| \) along the undulator, and requirement that the frequency spread \( |(\omega - \omega_r)/\omega_r| < 1/(2N_a) \), where \( \omega_r \) is resonance frequency of radiation at zero angle. Result in the moving frame follows from relativistic invariance of \( d^3k/\omega \).

The normalized vector potential is obtained by multiplying Eq.(12) by \( \sqrt{\Omega} \). Parameter of interaction with the mode is then \( g = g_k \sqrt{\Omega} \) and, using time of the interaction in the moving frame \( t = 2\pi N_a/(ck) \), we get \( gt = (K_0/\sqrt{1 + K_0^2}) \sqrt{e^2/\hbar c} \), i.e. \( (gt)^2 \) of the order of \( \alpha_0 = e^2/\hbar c \).

Interaction of particles with the mode described by Hamiltonian Eq. (11) is just back-scattering of equivalent photons. Initial state \( |p_i, n> = |p_1, p_2, \ldots, p_{N_B}, n> \) of the system with \( n \)-photons and particles with momentums \( p_i \), \( i = 1 \ldots N_B \) is transformed by the interaction with the mode \( k = \omega/c = \kappa k_u \) to the vector \( |\Psi(t)> \), which is the solution of the Schrodinger equation [7],

\[ |\Psi(t)> = \sum_{l, p_i} |p_i - 2\hbar k l, n + l\Sigma> \sqrt{\frac{n!}{(n + l\Sigma)!}} \int \frac{d\psi}{2\pi} e^{-i\hbar \psi} e^{-i\omega t(n + l\Sigma)} \Pi_{i=1}^{N_B} F_n(t, p_i, l). \]
Here \( l_\Sigma = \sum_i l_i \) is total number of radiated photons, \( E(p_i, l_i) = (p_i - 2hk l_i)^2 / (2m_0) \),

\[
F_n(t, p, l) = \int_0^\infty \frac{d\lambda}{n!} e^{-\lambda} \hat{\Omega}_{\lambda\kappa}(\frac{\lambda a_t}{\kappa a_t^*})^{1/2} J_l(2g|a_t|\sqrt{\lambda\kappa}) e^{-(it/\hbar)E(p_i,l_i)} e^{i\lambda\psi} |_{\kappa=1}.
\]  

(15)

The operator \( \hat{\Omega}_{\lambda\kappa} = e^{-(1/2)\frac{\hbar^2}{2m_0}} \), \( J_l \) is Bessel functions, and

\[
a_i(t) = \frac{\sin(\epsilon_i l/2)}{(\epsilon_i/2)} e^{-\epsilon_i t/2}, \quad \dot{a}_i(t) = e^{-\epsilon_i t}, \quad \epsilon_i = \frac{2kp_i}{m_e}.
\]  

(16)

The integration over \( \psi \) is introduced to separate parameters of radiation and of the particles.

As the main simplification [4] of the theory, terms of the order of \( \hbar k^2 / m_e \) are neglected,

\[
\frac{\hbar k^2 t}{2m_0} \simeq \pi N_0 k \lambda_{\text{Compt}} \ll 1.
\]  

(17)

As a result, we loose effect of bunching due to radiation. However, this is sufficient for our purpose.

For short undulators, \( kpt / m_e < 1 \), \( \frac{\sin(\epsilon_i t/2)}{(\epsilon_i/2)} \simeq t \). The function \( F_n \) depends on parameter \( gt \), where \( t \) is time of flight in the undulator \( (t = N_0 \lambda_\text{w} / (c\gamma) \) in the moving frame).

In the case of a single particle and \( n \) initial photons,

\[
F_n(t, p, l) = (ga)^{1/2} e^{-(1/2)(ga)^2} L_n^{1/2}(g^2|a|^2),
\]  

(18)

what reproduces Dattoli-Renieri result [4].

Initial density matrix

\[
\dot{\rho}(0) = |p', \Sigma' > \rho(p', p, \Sigma', \Sigma') < p, \Sigma|,
\]  

(19)

is transformed to

\[
\dot{\rho}(t) = |\Psi(t) > \rho(p', p, \Sigma', \Sigma') < \Psi(t)|.
\]  

(20)

IV. DENSITY MATRIX OF THE UNDULATOR

Let us simplify the density matrix Eq. (20).

We assume that at the entrance to the pickup there is no radiation, \( n = 0 \). In this case, initial density matrix

\[
\dot{\rho} = \Pi_{i=1}^{N_0} |p'_i > \rho(\nu'_i, p_i) < p|
\]  

is transformed according to Eqs. (14), (20) to \( \dot{\rho}(t) = |q', \Sigma' > \rho(q', q, \Sigma, \Sigma') < q, \Sigma| \), where

\[
\rho(q', q, \Sigma, \Sigma') = \frac{1}{\sqrt{\Sigma_\Sigma'!}} \int d\psi d\psi' (2\pi)^2 e^{-i(\Sigma' - \Sigma)\psi} e^{i\omega t(\Sigma' - \Sigma)} \int d\lambda d\lambda' e^{-\lambda - \lambda'} \hat{\Omega}_{\lambda\kappa} \hat{\Omega}_{\lambda'\kappa'} F_{\text{loc}}(q', q).
\]  

(21)

Here \( |q > \) stands for the set \( |q_1...q_{N_0} > \), \( F_{\text{loc}}(q', q) = \Pi_{i=1}^{N_0} F_{\text{loc}}^i(q'_i, q_i) \),

\[
F_{\text{loc}}^i(q'_i, q_i) = \sum_{l, l'} f_{l} f_{l'}^* \rho(\nu'_i + 2hkl'_i, q_i + 2hkl_i) e^{-\frac{(q'^2 - q^2)}{2m_e\hbar}},
\]  

(22)

\[
f_i = f(q, l, \psi), \quad f'_i = f(q'_i, l'_i, \psi'),
\]  

(23)

It is convenient to consider Fourier transform

\[
F_{\text{loc}}(p, z) = \int \frac{L dq}{2\pi \hbar} e^{iqz / \hbar} F_{\text{loc}}^i(p + q/2, p - q/2).
\]  

(24)
For a short undulator, parameter $\epsilon t << 1$. In this case, $a(t) \simeq te^{-i\epsilon t/2}$. Parameter $(gt)^2$ has the meaning of the average number of photons radiated in the undulator per particle and is always small. This justifies expansion of $f_i$ in series over $gt$. Neglecting terms of the order of $(gt)^3$, we write for the $i$-th particle
\[
F_{ioc}^i(p, z) = F_{ioc}^0(p, z)(1 + gtF_{ioc}^{(1)} + (gt)^2F_{ioc}^{(2)}),
\]
deleting the term $(gt)^3$.

where
\[
F_{ioc}^0(p, z) = \frac{\hbar}{\sigma} \left( \frac{(p-m_e)^2}{2\Delta^2} - \frac{(x-x_0 - pt/m_e)^2}{2\sigma^2} \right),
\]
and
\[
F_{ioc}^{(1)} = e^{-(1/2)(\hbar k/\Delta)^2}\left\{-\kappa e^{\hbar k(p_0 - p)/\Delta} - \kappa' e^{\hbar k(p_0 - p)/\Delta} + \lambda e^{-\hbar k(p_0 - p)/\Delta} + \lambda' e^{\hbar k(p_0 - p)/\Delta}\right\},
\]

$F_{ioc}^{(2)}$ has a similar structure.

With the same accuracy,
\[
F_{ioc}^i(p, z) = \left\{\Pi_{i=1}^{N_b} F_{ioc}^0(p_i, z_i)\right\} e^{gt\Sigma_i F_{ioc}^{(1)} + (gt)^2\Sigma_i F_{ioc}^{corr}},
\]
where $F_{ioc}^{corr} = F_{ioc}^{(2)} - (1/2)\left[F_{ioc}^{(1)}\right]^2$. Eq. (28) takes into account all terms of the order of $N_bgt$ and $N_b(gt)^2$ neglecting terms $N_b(gt)^3$.

The sum
\[
f_0 = gt \sum_i F_{ioc}^{(1)}
\]
in the exponent of Eq. (28) is defined by parameters
\[
\sigma_\pm(p, z) = \frac{\hbar}{\sigma} \left\{\int_{-\pi/2\sigma}^{\pi/2\sigma} e^{2i\tilde{k}(z_i - p_0)} e^{-\hbar k(p_i - p_0)/\Delta} e^{-\hbar k/2\Delta^2} s_i\right\}.
\]

This expression has to be averaged over frequency spread in the mode around $\tilde{k} = \gamma k_u$.

\[
\sigma_\pm(p, z) = \frac{\hbar}{\sigma} \left\{\int_{-\frac{\pi}{2\sigma}}^{\frac{\pi}{2\sigma}} e^{-2i\tilde{k}(z_i - p_0)} e^{-\hbar k(p_i - p_0)/\Delta} e^{-\hbar k/2\Delta^2} s_i\right\}.
\]

where
\[
s_i = \int dk \frac{e^{-2i(k-\tilde{k})(z_i - p_0)/2m_e\gamma}}{(\pi N_u(k - \tilde{k})/\Delta)^2} \sin^2\left(\frac{\pi N_u(k - \tilde{k})/\Delta}{\pi N_u/k} \right)\sin^2\left(\frac{\pi N_u(k - \tilde{k})/\Delta}{\pi N_u/k} \right).
\]

Factor $s_i$ restricts summation over particles within the length $\propto 2\pi N_u/(2\tilde{k})$ (the length of a "slice"); or, in the laboratory system, within $l_s = N_u\lambda_{lab}$. Parameter $N_u = \langle\sigma - \sigma^*\rangle /\langle(gt)^2\rangle$ is the fundamental parameter of the theory defining number of interacting particles within the bandwidth of the mode (number of particles per slice). Here double averaging means averaging with the density matrix of the wave packet Eq. (26) and over $z_0, p_0$ within the Gaussian bunch $\rho_B(z_0, p_0) = (1/2\pi\sigma_B\Delta_B)e^{-p_0^2/2\Delta^2 - z_0^2/2\sigma^2}$. If the width of the packet $\sigma$ is of the order of the length of a slice and $N_u >> 1$, then $k\sigma >> 1$, and
\[
N_s = \frac{\int dx \sin^2 x \int dy \sin^2 y}{x^2 \pi y^2} \ll e^{-\frac{2\pi}{\Delta B}(x-y)(z_i - p_0)}.
\]

Neglecting terms of the order of $h$, we get
\[
N_s = N_u \frac{\sqrt{2\pi}}{3k\sigma_B},
\]
where $\sigma_B$ is the rms bunch length in the moving frame and we use $f((dx/\pi)(\sin x/x)^4 = 0.6666$. In terms of the wave length of the mode and the bunch length in the laboratory frame, 

$$N_s = N_B \left( \frac{-N_0 \lambda_L}{3\sqrt{2\pi} \sigma_B^3} \right).$$  \hfill (35)

In terms of averaged $\sigma_{\pm}$, Eq. (31),

$$f_0(\psi, \psi') = -\kappa \sigma_+ e^{i \psi} - \kappa' \sigma_+^* e^{-i \psi'} + \lambda \sigma_- e^{-i \psi'} + \lambda' \sigma_- e^{i \psi'}.$$  \hfill (36)

The second terms $(gt)^2 \Sigma_i F_i^{\text{corr}}$ in the exponent of Eq. (28) can be expanded over $h$. Expansion starts with the term proportional to $h^2$. It can be split in two parts: one,

$$f^{(1)}_{\text{cor}} = -N_s (gt)^2 \left( \frac{h k}{\Delta} \right)^2 (\kappa e^{i \psi} + \lambda e^{-i \psi'})(\kappa' e^{-i \psi'} + \lambda e^{i \psi'}),$$  \hfill (37)

which is proportional to the number of particles $N_s$, and $f^{(2)}_{\text{cor}}$, proportional to the sum over oscillating factors. Introducing $r_\pm = \Sigma_i e^{\pm 4i k (z_i - p_i/2m_\nu)}$, we can write

$$f^{(2)}_{\text{cor}} = -\frac{(gt)^2}{2} \left( \frac{h k}{\Delta} \right)^2 [(\kappa e^{i \psi} + \lambda e^{-i \psi'})^2 r_+ + (\kappa' e^{-i \psi'} + \lambda e^{i \psi'})^2 r_-].$$  \hfill (38)

In these notations,

$$F_{\text{loc}}(p, z) = \{ \Pi_i^{N_p} F_i^0(p_i, z_i) \} e^{f_0(\psi, \psi') + f^{(1)}_{\text{cor}} + f^{(2)}_{\text{cor}}}.$$  \hfill (39)

The first factor is the product of unperturbed single particle distribution functions while exponent describes particle interaction. The last term, $f^{(2)}_{\text{cor}}$, is small. Eq. (28) can be simplified writing $e^{f^{(2)}_{\text{cor}}} = (1 + f^{(2)}_{\text{cor}})$ and replacing $-gt \kappa' e^{-i \psi'}$, $gt \lambda e^{-i \psi'}$, and $gt \lambda' e^{i \psi'}$ by the derivatives over $\sigma_+^*$, $\sigma_-^*$, $\sigma_+$, and $\sigma_-$, respectively. The result is the differential operator $\hat{P}(\sigma_{\pm})$. The factor $e^{f^{(1)}_{\text{cor}}}$ can written as

$$e^{f^{(1)}_{\text{cor}}} = \hat{O}_{\mu, \nu} e^{-\nu(\kappa e^{i \psi} + \lambda' e^{-i \psi'}) - \mu(\kappa' e^{-i \psi'} + \lambda e^{i \psi'})} \big|_{\mu = \nu = 0},$$  \hfill (40)

where $\hat{O}_{\mu, \nu} = e^{-\xi^2 \frac{\mu^2}{2\pi}} \zeta^2 = N_s (gt)^2 \left( \frac{h k}{\Delta} \right)^2$. Then,

$$F_{\text{loc}}(p, z) = \{ \Pi_i^{N_p} F_i^0(p_i, z_i) \} (1 + \hat{P}) \hat{O}_{\mu, \nu} e^{-\kappa(\sigma_+ + \nu) e^{i \psi} - \kappa'(\sigma_+^* + \mu) e^{-i \psi'} - \lambda(\sigma_- + \nu) e^{-i \psi'} + \lambda'(\sigma_-^* - \nu) e^{i \psi'}}.$$  \hfill (41)

Now it is easy to calculate

$$\hat{O}_{\kappa, \lambda} \hat{O}_{\kappa', \lambda'} e^{-\kappa(\sigma_+ + \nu) e^{i \psi} + \lambda(\sigma_- + \nu) e^{-i \psi'} - \kappa'(\sigma_+^* + \mu) e^{-i \psi'} + \lambda'(\sigma_-^* - \nu) e^{i \psi'}} \big|_{\kappa = \kappa' = \lambda = \lambda'} = e^{(1/2)(\sigma_+ + \nu)(\sigma_-^* - \mu) + (1/2)(\sigma_-^* + \mu)(\sigma_+ - \nu)} e^{-\kappa(\sigma_+ + \nu) e^{i \psi} + \lambda(\sigma_- + \nu) e^{-i \psi'} - \kappa'(\sigma_+^* + \mu) e^{-i \psi'} + \lambda'(\sigma_-^* - \nu) e^{i \psi'}}.$$  \hfill (42)

Integration over $\psi$ and $\psi'$ can be carried out using

$$\int \frac{d\psi}{2\pi} e^{i \psi} e^{-i \psi} = \frac{\lambda}{\kappa}^{1/2} J_0(2\sqrt{\lambda \kappa}).$$  \hfill (43)

After that, integrals over $\lambda$ and $\lambda'$ are given by

$$\int_0^\infty d\lambda \lambda^{1/2} J_0(2\sqrt{\lambda a}) = a^{1/2} e^{-a}.$$  \hfill (44)

The distribution function at the end of the pickup

$$\rho(p, z, l_{\Sigma}, l_\xi) = \int \frac{L dq}{2 \pi h} e^{iqz/h} \rho(p + q/2, p - q/2, l_{\Sigma}, l_\xi),$$  \hfill (45)

takes form
\[ \rho(p, z, l'_{\Sigma}, l_{\Sigma}) = \frac{1}{\sqrt{l_{\Sigma}!l'_{\Sigma}!}} e^{i\omega t(l_{\Sigma} - l'_{\Sigma})} \{ \Pi_{i=1}^{N_b} F_{i}^{0}(p_i, z_i) \} (1 + \hat{P}) R(p, z), \]  

where

\[ R(p, z) = \hat{O}_{\mu, \nu}(\sigma^{+}_{-} - \mu)(\sigma^{+}_{-} - \nu)^{l_{\Sigma}} e^{-(1/2)(\sigma^{+}_{-} - \mu)(\sigma^{+}_{-} + \nu) - (1/2)(\sigma^{+}_{-} - \nu)(\sigma^{+}_{-} + \mu)}. \]

For small \( \zeta \), the density matrix at the end of the pickup is

\[ \rho(p, z, l'_{\Sigma}, l_{\Sigma}) = \frac{1}{\sqrt{\sigma_{-}!l'_{\Sigma}!}} \{ \Pi_{i=1}^{N_b} F_{i}^{0}(p_i, z_i) \} (1 + \hat{P}) R(p, z, N, \mu) e^{i\omega t(l_{\Sigma} - l'_{\Sigma})}, \]

where \( R = e^{-(1/2)(\sigma^{+}_{-} + c.c.)} \hat{R}(p, z, N, \mu) \), and

\[ \hat{R}(p, z, N, \mu) = \left( \frac{\sigma^{+}_{-}}{\sigma_{-}} \right)^{N} |\sigma_{-}|^{2N}, \quad N = \frac{l_{\Sigma} + l'_{\Sigma}}{2}, \quad \mu = \frac{l_{\Sigma} - l'_{\Sigma}}{2}. \]

Correction \( \zeta^{2}|\sigma_{-}|^{2} \) is of the order of \( N_{b}(gt)^{2} \frac{hk}{\Delta} \) and always negligible.

V. SOME RESULTS FOR THE UNDULATOR

Eq. (48) reproduces W. Becker and J. Mclver results obtained with the operator formalism. It gives the energy loss:

\[ <p> = \text{Tr}(\hat{p}\hat{\rho}) = -2hk(gt)^{2}, \]

and can be used to obtain the density matrix of radiation \( \rho_{\text{rad}} \),

\[ \rho_{\text{rad}}(l'_{\Sigma}, l_{\Sigma}) = \sum_{p} \rho(p, p', l'_{\Sigma}, l_{\Sigma}). \]

In the case of a single electron, \( N_{b} = 1 \), and the zero initial photons, the density matrix of radiation

\[ w_{\text{rad}}(l) = \rho_{\text{rad}}(l, l) = \frac{(gt)^{2l}}{l!} e^{-(gt)^{2}}, \]

is a coherent state. The average number of radiated photons in a single mode is small, \(<l> = (gt)^{2} = \alpha_{0} = 1/137. \) Fluctuations are large: \(<(\Delta l)^{2}> = <l^{2}> - <l>^{2} = <l> > > <l> >, and

\[ \frac{(\Delta l)^{2}}{<l>^{2}} = \frac{1}{(gt)^{2}} = 137. \]

Radiation of a bunch corresponds to the thermal statistics [6]

\[ \rho_{\text{rad}}(l'_{\Sigma}, l_{\Sigma}) = \delta_{l_{\Sigma}, l'_{\Sigma}} \frac{(\alpha)^{l_{\Sigma}}}{(1 + \alpha)^{l_{\Sigma} + 1}}, \quad \alpha = N_{b}(gt)^{2}. \]

For the following, it is convenient to transform the density matrix \( \rho(p, z, l'_{\Sigma}, l_{\Sigma}) \) back to the momentum representation,

\[ \rho(p + q/2, p - q/2) = \{ \Pi_{i} \int (dz_{i}/L) e^{-i(q' - q)z_{i}} \} \rho(q' + q/2, z_{i}). \]

The result is

\[ \hat{\rho} = |q', l'_{\Sigma} > \rho(q' q) < q, l_{\Sigma}|, \]

where

\[ \rho(q' q) = \frac{1}{\sqrt{l_{\Sigma}!l'_{\Sigma}!}} \{ \Pi_{i} \int \frac{dz_{i}}{L} F^{i}(q', q, z) \} (1 + \hat{P}) R(q' + q/2, z, N, \mu) e^{2i\mu t}, \]

and

\[ F^{i}(q', q, z) = \frac{h}{\sigma \Delta} e^{-i(q' - q)z/h} e^{-i\sigma_{+}^{2}(q' + q/2)^{2}} e^{-i\sigma_{-}^{2}((q' + q/2)^{2} - 2q'z).} \]

Note that \( \sigma_{\pm} \) are functions of the coordinates \( z_{i}, \frac{q' + q_{i}}{2} \) of all particles.
VI. OPTICAL AMPLIFIER AND DISPERSION SECTION

The density matrix Eqs. (48), (49) at the exit of the pickup undulator is the superposition of coherent states. Transformation of such a state in the optical amplifier can be obtained in the following way [8].

Let us consider the 2 level model of the amplifier with inverse population \( N_u > N_d \). Equation describing the time evolution of the density matrix is well known [12]:

\[
\dot{\rho} = -gN_u(aa^+ \rho + \rho a a^+) - gN_d[\rho a^+ + a^+ \rho - 2a \rho a^+].
\]  
(58)

Let us use the representation with fixed number of photons, \( \rho(t) = |n' > \rho(n', n, t) < n| \), and define \( F(N, \mu, t) \),

\[
\rho(n', n, t) = \frac{F(N, \mu, t)}{\sqrt{n! n'^!}}, \quad N = (n + n')/2, \quad \mu = (n - n')/2.
\]  
(59)

The function \( F \) is a solution of the Eq. (58). Parameter \( \mu \) is the integral of motion. Dependence on \( N \) can be obtained using Mellin transform

\[
F(N, \mu, t) = \int_0^\infty dz' G_m(N, z', \tau)f_0(z', m),
\]  
(60)

where \( \tau = gN_u t \), \( t \) is the amplification time, \( f_0 \) is given by the initial condition,

\[
f_0(z, \mu) = \int_{-\infty}^{i\infty} \frac{dN}{2\pi i} z^{-N} e^{N F(N, \mu, 0)}.
\]  
(61)

The kernel \( G_m \) can be obtained [8] for an arbitrary ratio \( N_u/N_d \). In the case of the full inverted population, \( N_d = 0 \),

\[
G_m(N, z', \tau) = (N - \mu) \frac{N}{z'} (1 - \frac{\xi}{\mu}) \frac{N}{z} (1 - \frac{\xi}{\mu}) L_{N-\mu}^2(-b).
\]  
(62)

where \( b = \frac{\xi}{(1-\xi)^{z'}}, \xi = e^{-2N_u g t}. \)

Consider, for example, radiation from the undulator of a single electron described by the initial coherent state

\[
\rho(n', n, 0) = \frac{\alpha^{n'} (\alpha^*)^n}{\sqrt{n! n'^!}} e^{-|\alpha|^2}.
\]  
(63)

Result of amplification is described by the density matrix

\[
\rho(n, n', t) = \frac{(N - \mu)!}{\sqrt{n! n'^!}} \frac{\alpha^{n'} (\alpha^*)^n e^{-|\alpha|^2}}{1 - |\xi|^2} \frac{(1 - \xi)^{N-\mu} L_{N-\mu}^2(-b).}{(1 - \xi)^{N-\mu} L_{N-\mu}^2(-b).}
\]  
(64)

The amplification factor is

\[
< a(t) >= \frac{\alpha}{\sqrt{\xi}},
\]  
(65)

what shows that parameter \( \xi \) defines the gain \( G \) of the amplifier, \( G = \frac{1}{\xi} \).

The lowest moments are:

\[
< a(t) >= \sqrt{G} \alpha, \quad < a^+ a >= G|\alpha|^2 + (G - 1),
\]  
(66)

and the signal-to-noise ratio is independent of \( G \) for \( G >> 1 \):

\[
\frac{< (a^+ a)^2 > - < a^+ a >^2}{< a^+ a >^2} = \frac{1 + 2|\alpha|^2}{(1 + |\alpha|^2)^2} \approx 1.
\]  
(67)

Let us use these results to transform the density matrix Eq. (49) in the amplifier.

The Mellin transform \( \tilde{R}_M(N, \mu) \) of \( \tilde{R}(\frac{q^2 + q}{2}, z, N, \mu) \),

\[
\tilde{R}_M(\zeta, \mu) = \int_{-\infty}^{i\infty} \frac{dN}{2\pi i} \zeta^{-N} \tilde{R}(\frac{q^2 + q}{2}, z, N, \mu),
\]  
(68)
is proportional to $\delta(\zeta - \zeta_0)$, $\zeta_0 = |\sigma_-|^2$,

$$\hat{R}_M(\zeta, \mu) = \zeta_0 \frac{\sigma_+^*}{\sigma_-} |\mu| \delta(\zeta - \zeta_0). \quad (69)$$

After the amplifier, $\hat{R}(\frac{q_q}{2}, z, N, \mu)$ should be replaced [8] by $F_{ampl}$,

$$F_{ampl}(N, \mu) = (N - |\mu|)! \sum_{\sigma_+} G_{\sigma_+} |\sigma_+\sigma_-| |\mu| (\frac{G - 1}{G})^N L^2_{N - |\mu|} \delta - |\sigma_-|^2). \quad (70)$$

Here $G$ is power gain of the amplifier, $L^2_{N}$ are Laguerre polynomials, and $N = (l_\Sigma + l_\Sigma')/2$, $\mu = (l_\Sigma - l_\Sigma')/2$.

Eq. (70) describes the amplification of the main term in Eq. (48). Calculation of the derivatives in the correction term, $\hat{P}R(p, z, N, \mu)$ where $\hat{P}$ is differential operator of the second order in $\sigma_\pm$, gives polynomial of the second order in $N$ multiplied by $R(p, z, N, \mu)$. The result can written as $\hat{P}(\frac{dy}{dp}) y^N$ where $\hat{P}$ is now a differential operator of the second order in $y$ independent of $N$, and $y = |\sigma_-|^2$, $x = \sigma_+^*/\sigma_-$. It can be transformed in the amplifier in the same way as the main term above.

VII. DISPERSION SECTION

Dispersion section with momentum compaction $c_{MC}$ and length $L_{ds}$, introduces $(z, p)$ correlation for each particle by changing the path length in the lab frame by $\Delta z = c_{MC}L_{ds}(p - p^0)/q_0$. In the moving frame, this corresponds to the classical distribution function

$$f(p, z) = \frac{1}{2\pi\Delta}\left(\frac{|p-p_0|^2}{\Delta^2} \right) e^{-\frac{(z-z_0-\nu p)^2}{2\Delta^2}}, \quad (71)$$

where parameter $\eta = \gamma_0 c_{MC}L_{ds}/m_e c$. The corresponding density matrix is different from Eq. (9) by the factor $e^{-(i/h)\eta(q^2 - q^2')/2}$.

Hence, the dispersion section modifies $F_i(q', q, z)$ in Eq. (56): Eq. (57) has to be replaced with

$$F_{\text{loc}}(q', q, z)e^{-(i/h)\eta|\sigma_+ - |\sigma_-|^2|/2}e^{i\theta}. \quad (72)$$

Here, a phase slip $\theta$ of a bunch centroid is added and should be controlled in the experiment.

VIII. KICKER

The density matrix at the entrance to the kicker is obtained by combining Eqs. (56), (71), and (73),

$$\hat{\rho}_{in}(t) = |q', l_\Sigma| \frac{F_{in}}{\sqrt{l_\Sigma!l_\Sigma!}} < q, l_\Sigma|,$$

where $F_{in} = F_{ds}(q', q)(1 + \hat{P})F_{ampl}(N, \mu)e^{2i\mu t} e^{-\frac{1}{2}|\sigma_+\sigma_- + c.c.|}$, and

$$F_{ds} = \int dz \frac{L}{\mathcal{L}} F_i(q', q, z)e^{-i\left[\frac{1}{2}[(q')^2 - q^2]\right]} \quad (74)$$

The transform of the density matrix at the exit of the kicker is given by Eq. (14) where $n$ has to be replaced by the number of photons $l_\Sigma$. We will use notation $m_i$ for the number of photons radiated by the $i$-th electron in the kicker and $m_\Sigma = \sum_i m_i$ for the total number of photons. We also assume that parameters of both undulators are the same.

Then, the density matrix at the exit of the kicker

$$\hat{\rho}_{out}(t) = |q' - 2km', l_\Sigma' + m_\Sigma' > \Phi_{loc}(q, q', \psi, \psi') F_{out}(q, l_\Sigma, m_\Sigma)$$

$$F_{out}(q', l_\Sigma', m_\Sigma')(1 + \hat{P})F_{ampl}(N, \mu)e^{2i\mu t} e^{-\frac{1}{2}|\sigma_+\sigma_- + c.c.|} < q, 2km, l_\Sigma + m_\Sigma|.$$

Here $l_\Sigma = N + \mu$, $l_\Sigma' = N - \mu$, $m_\Sigma = M - \mu$, $m_\Sigma' = M + \mu$. Because $l_\Sigma$ and $l_\Sigma'$ are positive, the range of summation is $0 < N < \infty$, $-N < M < \infty$, and $|\mu| < N$. Functions $\sigma_\pm$ in $F_{ampl}$ depend on coordinates of individual particles $\frac{q'+\eta}{2}, \frac{z_i}{}$. The operator $F_{out}$ is
\[
F_{\text{out}}(q, l_{\Sigma}, m_{\Sigma}) = \frac{1}{\sqrt{(l_{\Sigma} + m_{\Sigma})!}} \int \frac{d\psi}{2\pi} e^{-im_{\Sigma}\psi} e^{i\omega t(l_{\Sigma} + m_{\Sigma})} \int d\lambda \frac{\lambda^l}{l!} e^{-\lambda \hat{O}_{K}},
\]
and
\[
\Phi_{\text{loc}}(q, q', \psi, \psi') = \Pi_i \frac{dz_i}{L} F^{(i)}(q', q, z) e^{-\lambda \sum_{\mu}(q'_\mu - q_\mu)^2} |S^*_{m_i}(q, \lambda, \kappa) S_{l_i}(q', \lambda', \kappa')|,
\]
where
\[
S_{m_i}(q, \lambda, \kappa) = (\frac{\lambda a}{K\Delta})^{m_i/2} J_{m_i}[2g(a_j(t))\sqrt{\lambda\kappa}] e^{im_\psi} e^{-\frac{1}{2}[(q_{-} - 2hk\kappa)^2 + m^2_{\Sigma}]}.\]

To describe stochastic cooling, it is sufficient to calculate the momentum of a particle at the end of the kicker. The average moments for the \( j \)-th particle after a bunch passed through the system are \(<p_j^k>=Tr[\hat{J}_j^k\hat{\rho}_{\text{out}}(t)]\), \(k=0,1,...\), where \(\hat{J}\) is momentum operator and brackets \(<..>\) mean averaging over the wave packet. In the momentum representation, only the diagonal components, \(q'_i - 2hk\kappa m'_i = q_i - 2hk\kappa, i=1,2..N\) and \(l'_\Sigma + m'_\Sigma = l_\Sigma + m_\Sigma\), contribute in \(<p_j^k>\). We can utilize the fact that \(\sigma_{\pm}\) are functions only of the sum \(q' + q\) and introduce \(P, q'_i = P_i + hk(m'_i - m_i), q_i = P_i - hk(m'_i - m_i)\). This allows us to write
\[
<\hat{p}_j^k> = [P_j - hk(m_j + m'_j)]\Phi_{\text{loc}}(1 + \hat{P}) F^*_{\text{out}}(q, l_{\Sigma}, m_{\Sigma}) F_{\text{out}}(q', l'_{\Sigma}, m'_{\Sigma}) F_{\text{ampl}}(N, \mu),
\]
where
\[
\Phi_{\text{loc}} = \Pi_i \frac{dz_i dP_i}{2\pi\sigma\Delta} \rho_0(P_i, z_i) \sum_{m_i, m'_i} S_{m_i}(\lambda, \kappa) S_{m'_i}(\lambda', \kappa') e^{-2\Delta z'(z_i + \sigma P_i)(m'_i - m_i)},
\]
and
\[
\rho_0(P_i, z_i) = e^{-(P_i - p_i^0)^2/2\Delta^2 - (z_i - z_0 - P_i t/m_0)^2}.
\]

Note, that \(F_{\text{ampl}}\) depends on \(\sigma_{\pm}\) which are given now by Eq.(33) where \(p_i\) are replaced by \(P_i\).

Similarly to what was done for the pickup, we expand \(S(\lambda, \kappa)\) in series over \(gt\) neglecting terms \(o(gt)^3\). We skip over details of calculations and give the final result:
\[
<\hat{p}_j^0> = \sum_{\neq j} \hat{K}_n(1 + \hat{P}) F_{\text{out}}(q, l_{\Sigma}, m_{\Sigma}) F_{\text{out}}(q', l'_{\Sigma}, m'_{\Sigma}) Q(b_1, \mu) F_{\text{ampl}}(P, z)|_{b_2 -> b_1}.
\]

Here the sum stands for integrals \(\Pi_i \frac{dz_i dP_i}{2\pi\sigma\Delta} \rho_0(P_i, z_i)\) over all particles in a bunch, and
\[
Q(b_1, \mu) = e^{\lambda b_1 e^{i\phi} - \kappa b_1' e^{-i\phi} + \lambda b_1 e^{i\phi} - \kappa b_1' e^{-i\phi}},
\]
where \(b_1 = gt \sum \phi \theta^{-i\phi}\), and phase \(\phi_j = 2k[z_j + p_j\eta]\). Operators \(\hat{K}_n\) for different \(n = 0, 1, 2\) are: \(\hat{K}_0 = 1, \hat{K}_1 = q_j - hkg(\alpha - \alpha_\kappa), \hat{K}_2 = \hat{K}_1^2 + (hk)^2 g t(\alpha + \alpha_\kappa),\)
\[
a_\kappa = e^{-i\phi} \frac{\partial}{\partial b_2} + e^{i\phi} \frac{\partial}{\partial b_2'}, a_\kappa = e^{i\phi} \frac{\partial}{\partial b_1} + e^{-i\phi} \frac{\partial}{\partial b_1}.
\]
Eq. (82) after some calculations, see Appendix, can be written as:
\[
<\hat{p}_j^n> = \sum_{\neq j} \hat{K}_n \sum_{\mu}(1 + \hat{P})^{\lambda\mu} \int_{\sigma} [2\sqrt{G}|b_2 - b_1| |\sigma - \sigma_j + |^2]
\]
\[
(b_1 - b_2) e^{(G-1)|b_2|} |b_2| (2(1/2)|b_2|^{1/2} + c.c.) e^{(1/2)|\sigma_j - \sigma_j + c.c.|}.\]

The operators \(\hat{K}_n\) are not more than the second order differential operators in \(b_2, b_1\) and the function depends only on \(b_2, b_1\). Therefore, it is sufficient to take into account only terms \(\mu = 0, \mu = \pm 1\) in the sum over \(\mu\). Additionally, we can expand the answer in series over \(gt\) and neglect terms \(o(gt)^3\).

To check the result, we can calculate the average \(<\hat{p}_j^n>\) for \(n = 0\). This quantity is just the norm of the distribution function and has to be equal one. Indeed, the answer is different from one by the term of the order of \(N^2(gt)^4(hk/\Delta)^4\).
The result for the moments $n = 1$ and $n = 2$ were obtained with MATHEMATICA. As it will be shown below, the power gain $G$ has to of the order of $\Delta_0/(\hbar k)$. Hence, $G >> 1$ and we can neglect terms which are independent of $G$. In this approximation, momentum $\tilde{p}_j$ of the $j$-th particle at the end of the kicker is

$$\tilde{p}_j = p_j - 2(\hbar k^2 / G^2) \sin \theta_{e\ell} e^{-2ikz_j + i\phi} + c.c.,$$  

(86)

where $\eta_{e\ell} = \eta + t/2m_e$, and $\theta$ is phase slip of the bunch centroid. Calculation of $\tilde{p}_j^2$ at the end of the kicker gives

$$\tilde{p}_j^2 = p_j^2 - 4G(\hbar k)^2 (\hbar k) p_j (\sigma_0^2 e^{-2ikz_j + i\phi} + c.c.) + 8G(\hbar k)^2 (1 + (\hbar k)^2 \sigma_0 \sigma_0^* + c.c.)$$  

(87)

$$+ 4\sqrt{G}(\hbar k)^2 (\hbar k)^2 (b_1 \sigma_0^* e^{i\phi} + c.c.).$$  

(88)

Here $\sigma_0 = \sigma_{\pm}|_{h \to 0}$. Double averaging over the wave packet $\rho_0(p_j, z_j)$ and over Gaussian distribution of particles in the bunch gives the rms $\Delta^2 = \langle p^2 \rangle - \langle p \rangle^2$ at the end of the kicker:

$$\frac{\Delta^2 - \Delta_0^2}{\Delta^2} = -16\sqrt{G}(\hbar k)^2 \frac{b_0}{\Delta_0^2} \Lambda \sin \theta + 8G(\hbar k)^2 (\hbar k)^2 [1 + N_s(\hbar k)^2]$$  

$$+ 8\sqrt{G}(\hbar k)^4 (\hbar k)^2 N_s \cos \theta e^{-2(k\Delta_0)^2\eta_{e\ell}}.$$  

(89)

Here $\Lambda = k\Delta_B \eta_{e\ell} e^{-2(k\Delta_B \eta_{e\ell})^2}$. To get damping, we have to choose $\sin \theta = 1$. The damping is maximum if the power gain $G$ of the amplifier is equal to

$$\sqrt{G} = \frac{\Lambda}{(\hbar k/\Delta_B)[1 + N_s(\hbar k)^2]}.$$  

(90)

Parameter $\Lambda$ as function of $x = k\Delta_B \eta_{e\ell}$ has maximum value $\Lambda_{max} \approx 0.3$ at $x \approx 2$. This defines the optimum parameter $\eta$ of the dispersion section.

The optimized reduction of the rms energy spread in one pass through the system is

$$\frac{\Delta^2 - \Delta_0^2}{\Delta^2} = -\frac{8\Lambda_{max}^2}{(\hbar k)^2 + N_s}.$$  

(91)

IX. CONCLUSION

The one pass reduction of the energy spread rms is derived following the evolution of the density matrix through all components of the system. The consideration is fully quantum-mechanical both for the beam and for the radiation but bunching effect is neglected and length of a slice of the order of $N_a \lambda_{lab}$ is assumed to be small compared to the bunch length in the laboratory frame $s_{LAB}^L$.

The final result Eq. (91) has the form equivalent to the classical equation for stochastic cooling with quantum noise $1/(\hbar k)^2$. Eq. (91) for large $N_s >> 1/(\hbar k)^2$ corresponds to classical theory of stochastic cooling: the damping rate is given by the number of particles $N_s$ per slice. However, for small $N_s$ the damping rate goes to a constant proportional to $1/(\hbar k)^2$, where $(\hbar k)^2 \propto (K_2^2 + 1 + K_2^2)\alpha_0$. The quantum fluctuations set the limit on the damping rate: the minimum number of turns for cooling is of the order of $1/\alpha_0$. The term $1/(\hbar k)^2$ is equivalent to the noise induced by 1/00 particles and is related to the quantum limit of the input noise of the amplifier equal to one photon in a mode. The cooling is the result of interference of the amplified mode with the mode radiated in the kicker. The other quantum mechanical corrections are small, of the order of $(\hbar k)/\Delta_B$ (i.e. $\hbar k_{LAB}/\Delta_{PL}$ in the laboratory frame) and can be noticeable only for very cold beams with energy spread comparable with the photon energy.

We are thankful to A. Zholentz for useful discussions. Work supported by Department of Energy contract DE–AC03–76SF00515.
XI. APPENDIX

Eq. (82) can be simplified, first, integrating over $\psi$ and $\psi'$ and then by $\lambda$ and $\lambda'$ using formula:

$$\int d\lambda \frac{\lambda^{L}}{L!} e^{-\lambda \hat{O}_{\hat{\lambda}K}(\frac{\lambda}{K})^{m}/2 J_{m}(2\sqrt{\lambda K})} |_{\lambda=1} = b_{n}/e^{-b/2}L_{n}^{(m)}(b),$$

(92)

It can be obtained expanding Bessel function and gives result in terms of Laguerre polynomials $L_{n}^{(m)}$. Eq. (92) is valid both for $m > 0$ and $m < 0$, where $L_{q}^{-m}(b)$ has to be understood as

$$L_{q}^{-m}(b) = (-1)^{m} \frac{(-m)!}{m!} b^{m} L_{q}^{-m}(b).$$

(93)

In this way we obtain

$$F_{out}(l_{x}, M_{x}) F_{out}(l_{y}, M_{y}) Q(b_{1}, b_{2}) = (b_{2})^{M-\mu} (b_{1})^{M+\mu} e^{-\frac{1}{2}b_{2}b_{1}^{*}} L^{M-\mu}_{N+\mu} (b_{2}) L^{M+\mu}_{N-\mu} (b_{2} b_{1}).$$

(94)

where $b_{1} = g_{t} \sum e^{2ikz}$. The average, $< p_{j}^{k} >$ is proportional to the sum

$$S(\mu) = \sum_{M = -\infty}^{\infty} x_{M}^{0} \sum_{N = -\infty}^{\infty} \left( \frac{N + \mu}{N - \mu} \right)! \left( \frac{G - 1}{G} \right)^{N} I_{N+\mu}^{M-\mu}[x] L^{M+\mu}_{N-\mu}[x] - \frac{y}{G - 1},$$

(95)

where $y = |G_{s}|^{-2}$, $x = b_{2}b_{1}^{*}$, and $x_{0} = |b_{1}|^{-2}$. Terms $\mu < 0$ can be obtained by complex conjugation.

The sum $S(\mu)$ can be split in two parts: one, for $-\mu < M < 0$, $\mu < N < \infty$, and another for $-\infty < M < -\mu$, $-M < N < \infty$. In the first sum we may start summation from $N = -\mu$ because the maximum power of $z$ in $L^{M-\mu}_{N+\mu}(z)$ is $N + \mu$ and, therefore, derivatives over $z$ give zero if $N < \mu$. After this, the sum can be calculated, first, expressing $I_{N-\mu}^{2\mu}[-y]$ in terms of the confluent hypergeometric factor and using integral representation for the last one,

$$I_{N-\mu}^{2\mu}[-y] = \frac{(N + \mu)!}{(N - \mu)!} e^{-y} e^{y} \int_{-i\infty}^{i\infty} ds \frac{y^{N-\mu}}{(s - 1)^{N+\mu+1}}.$$  

(96)

Secondly, we write $L^{M-\mu}_{N+\mu}(z) = (\frac{\partial}{\partial z})^{2\mu} I_{N+\mu}^{M-\mu}(z)$, and use [9]

$$\sum_{N = -M}^{\infty} \frac{(N + \mu)!}{(N - \mu)!} L^{N+\mu}_{M-\mu}(x) L^{M-\mu}_{N+\mu}(z) = \frac{(\xi x z)^{-(M-\mu)/2}}{1 - \xi} e^{-\xi x z / (1 - \xi)} I_{M-\mu}(\frac{2\sqrt{\xi x z}}{1 - \xi}),$$

(97)

where $\xi = (x^{2} - (\lambda + \lambda')^{2})/G^{2}$. In this form, the answer is valid also for the second part of the sum, $-\infty < M < -\mu$, $-M < N < \infty$.

The sum over $M$,

$$S(\mu) = (\frac{\partial}{\partial z})^{2\mu} \sum_{M = -\infty}^{\infty} \frac{x_{M}^{0}}{y^{2}} e^{-y} \int_{-i\infty}^{i\infty} ds \frac{(\xi x z)^{-(M-\mu)/2}}{1 - \xi} e^{\xi x z / (1 - \xi)} I_{M-\mu}(\frac{2\sqrt{\xi x z}}{1 - \xi}),$$

(98)

can be calculated using

$$\sum_{k = -\infty}^{\infty} \alpha^{k/2} I_{|k|}(2\beta) = e^{2\alpha + \beta \sqrt{\alpha}}.$$  

(99)

After that, each derivative over $z$ gives the factor $(\frac{\xi x z}{1 - \xi})(1 - \frac{x}{x_{0}}).$ $S$ takes form

$$S(\mu) = y^{-2\mu} \frac{x^{0} e^{-y}}{y^{2}} \int_{-i\infty}^{i\infty} ds \frac{e^{s y} e^{\xi x z / (x_{0} - 1) + x_{0} - \xi x z / (1 - \xi)}}{1 - \xi} (1 - \frac{x}{x_{0}})^{2\mu} G^{\mu+1}(G - 1)^{\mu} (s - G)^{2\mu+1}. $$

(100)

The integral here is given by the residues of the poles at $s = G$,

$$S(\mu) = G^{G - 1} \frac{\alpha^{x_{0} / (\lambda + \lambda')^{2}}}{x_{0}^{2\mu}} (1 - \frac{x}{x_{0}})^{2\mu} I_{2\mu} (2\sqrt{GAy}) e^{x_{0} \alpha / (G - 1)^{2}}.$$  

(101)
where $A = |b_2 - b_1|^2$. Finally,

\[
< p_j^n > = \sum_{i \neq j} \hat{K}_n \sum_{\mu} (1 + \hat{P}) \left( \frac{\sigma_+}{\sigma_-} \right)^\mu I_{2\mu} \left[ 2 \sqrt{G} |b_2 - b_1|^2 |\sigma_- - \sigma_+|^2 \right]
\]

(102)

\[
\left( \frac{b_1 - b_2}{b_1^* - b_2^*} \right) \mu e^{(G-1)|b_2 - b_1|^2 + (1/2)[b_2(b_2^* - b_1^*) + c.c.] + (1/2)[\sigma_- (\sigma_-^* - \sigma_+^*) + c.c.]} |b_2 = b_1^*.
\]

(103)
